ATLANTA, GEORGIA 30333

Vol. 12 No. 45

PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED NOVEMBER 9, 1963

POLIOMYELITIS - Six cases of poliomyelitis, all paralytic, were reported for the week ending November 9. Two cases were reported from Georgia, and single cases were reported from Michigan, Alabama, Texas, and Florida. The nation's total thus far in 1963 remains well below one-half that reported for a comparable period last year.

Florida has reported 10 cases of paralytic poliomyelitis thus far in 1963. Of this total, 4 have occurred in Jacksonville. All 4 cases have yielded Type I polio virus. Of the 4 Jacksonville cases, 3, including the case reported this week, have ended fatally. All deaths have occurred within the past 4 weeks. The most recent case was a 28-year-old Jacksonville woman, an aunt of a 2-year-old male who died of poliomyelitis on October 25. All Jack-

sonville victims have been unvaccinated Negroes. Additional suspect cases are under surveillance.

#### **EPIDEMIOLOGICAL REPORTS**

#### Botulism - Smoked Fish Products - United States

Smoked products made from Great Lakes fish or processed in establishments in the Great Lakes region henceforth will be stored and distributed as a frozen food, according to a release made jointly by the National Fisheries Institute and the Food & Drug Administration.

This action follows the Food & Drug Administration's recommendation three weeks ago that all products made from such fish then on the market should be destroyed (see MMWR, Vol. 12, p. 358).

The distribution of smoked fish as a frozen item is considered safe because the botulism toxin is not known to develop below freezing temperature, according to the FDA. Because the near-zero temperatures normally expected of perishable frozen foods may adversely affect the quality of certain smoked fish products, such frozen smoked fish will be distributed under conditions which will assure that it is held at all times in the frozen state, but not necessarily at the low temperatures generally employed for other frozen prepared foods. Available facts indicate that no additional protection would be afforded by the lower temperatures, as long as the product is maintained continuously in the frozen state, according to the FDA. (Distribution of the fish according to the above manner will be subject to certain State and local requirements, however, which may specify temperatures at or near zero.)

The FDA considers these measures adequate to prevent botulism while technological studies are being made to develop practices for long-range application.

#### Dengue Fever — Florida

A case of dengue fever in a 28-year-old, white female who had visited Puerto Rico has been reported from Florida. While in San Juan, this patient consulted a physician because of her complaints of fever, eyeball pain, sweating, and weakness. The next day she returned to Miami. A scarlatiniform rash appeared on the fourth day of her illness.

Blood specimens collected in Florida on the third and fourth days of illness were examined for St. Louis and Dengue I HI antibodies. The results are as follows:

Day of Illness	St. Lauis	Dengue I
3	1:20	< 1:20
4	1:160	> 1:160

Because the patient had been in Puerto Rico for the 18 days prior to the onset of her symptomatology, the case has been classified by Florida officials as one of imported dengue fever.

Morbid

No secondary cases of dengue are known to have occurred in Florida.

(Reported by C. M. Sharp, M.D., Acting Director, Bureau of Preventable Diseases, Florida State Board of Health; John E. Davies, M.D., Director of Research and Epidemiology, Florida State Board of Health; and Dr. William Pond, University of Miami Infectious Disease Research Laboratory.)

Editor's Note: This is the 16th imported case of clinical dengue fever reported to the Communicable Disease Center thus far in 1963. Other cases occurred in Michigan, New York, and Minnesota (see MMWR, Vol. 12, pp. 270, 308, and 310). All victims are believed to have acquired the disease while in either Jamaica or Puerto Rico where there have been epidemics of dengue-like fever.

#### Microsporum canis — Nebraska

Within five days after the acquisition of a kitten, six children in one family developed ringworm-like lesions which appeared over the trunk and extremities. No lesions occurred in the hair. Fluorescence occurred upon examination under a Woods lamp. On culture, the lesions grew Microsporum canis.

This family had purchased the kitten from a local kennel in another section of the city, and because of the temporal relationship the family reported this incident. A health department representative was scratched by a playful kitten during his investigation of the kennel; he could not find evidence of lesions at that time.

Less than two weeks later, the investigator was bothered by two itchy, distinct, slightly raised, dimeshaped lesions at the site of the cat scratch. The investigator was puzzled until he read the report of the cultures from the above family. He suspected that he, too, was a victim of the same disease. Woods lamp fluorescent was positive. Cultures confirmed his suspicion.

Another investigator discovered that a family of eight children also had been victims of Microsporum canis, proved by culture, which likewise had recently acquired a kitten from the same kennel. These two families lived in different sections of the city and their only mutual contact was the kittens acquired from the same kennel. This investigator also became a victim of this infection.

The kittens were cultured and growth revealed Microsporum canis from the axillary and inguinal hairs, areas where apparently the sun did not kill the organism.

The kennel was found to be unlicenced and operating in an area which was not zoned for such business; subsequently, it has been closed. A humane society employee, who came to remove the kittens from the kennel, became the third adult victim.

At least 18 cases, including the two health department investigators and the humane society worker were uncovered in the investigation. One secondary case included in this total occurred in the child of one of the investigators. There were no pets in his family and it is presumed that the case was acquired from the father.

Of interest is the fact that all the children in each of these two families acquired the infection — that is, six of the six in the first family and eight of the eight in the second family.

(Reported by E. D. Lyman, M.D., M.P.H., Health Director, Omaha-Douglas County Health Department, E. A. Rogers, M.D., Director of Health, Nebraska State Department of Health, and an EIS Officer.)

#### Poliomyelitis Surveillance Summary - 1962

There were 683 cases of paralytic poliomyelitis submitted on individual case forms to the Poliomyelitis Surveillance Unit of the Communicable Disease Center during 1962. These cases have been corrected for verification of diagnosis 60 days or longer after onset of illness. When such a follow-up report was not submitted, the preliminary diagnosis has been retained.

The paralytic cases are presented in the following table by age group and vaccination history. The table includes 666 cases with residual paralysis at 60 days, plus 17 cases with a preliminary diagnosis of paralytic poliomyelitis for which no 60-day report was received.

Of the 683 paralytic cases, 49 percent occurred in pre-school age children, compared to 39 percent in 1961 and 43 percent in both 1960 and 1959. The paralytic cases are presented in the following table by age group and history of immunization with inactivated poliomyelitis vaccine.

TABLE 1

There were 47 fatalities attributed to poliomyelitis for 1962, 43 of whom had bulbar involvement.

The fatalities are presented in the following table by age group and by history of immunization with inactivated poliomyelitis vaccine, together with the paralytic case fatality rate (per 100) for each age group.

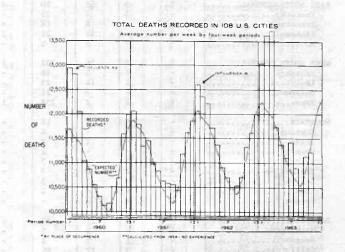

(continued on page 384)

#### TOTAL DEATHS REPORTED IN 108 CITIES

The weekly average number of total deaths in 108 cities for the four-week period ending November 9 was 11,233 as compared with an expected weekly average of 11,306.

TABLE 2
POLIOMYELITIS FATALITIES BY DOSES OF INACTIVATED
VACCINE AND AGE GROUP, UNITED STATES, 1962

		oses	of	Inact	cine	Total Paralytic	Case Fatality	
Age Group	0	1-2	3	4+	Unknown	Total	Cases	Rate(%)
0-4	11	0	0	3	1	15	338	4.4
5-9	2	1	1	3	0	7	139	5.0
10-19	5	4	2	0	0	-11	96	11.5
20-29	5	0	0	0	1	6	52	11.5
30-39	4	0	0	0	0	4	36	11.1
40+	3	0	0	0	1	4	22	18.2
Total	30	5	3	6	3	47	683	6.9

As in past years, the paralytic case-fatality rate increased with age, showing a step-wise increase in the age groups 0-9 to 10-39 to over 40 years of age. The overall paralytic case-fatality rate of 6.9 per 100 compares with 9.3 in 1961, 9.5 in 1960, 8.3 in 1959, and 7.4 in 1958.

## INTERNATIONAL NOTES - QUARANTINE MEASURES International Certificates of Vaccination

Reports have been received by the Division of Foreign Quarantine of the U. S. Public Health Service that many persons traveling abroad have their immunizations recorded either on a physician's prescription blank or have the international vaccination document improperly completed. Consequently, in some instances, these travelers are being detained at international ports of entry.

International travelers should be warned that smallpox and cholera vaccinations, when required for international travel, must be recorded on the World Health Organization approved International Certificates of Vaccination form, and all information must be complete, including the "Approved Stamp", which is the stamp of the local or State Health Department. Other approved stamps include those of the Department of Defense, Public Health Service, and those special stamps issued by the latter agency.

#### **ERRATA**

In the line listing of malaria cases aboard the M/V Ranborg (see MMWR, Vol. 12, p. 367), the onset date listed for Case No. 2, Chief Steward, is incorrect. It should read October 11 rather than October 4.

Two typographical errors appeared in the table listing the 12 most prevalent salmonella serotypes identified from human and non-human sources in the United States in MMWR, Vol. 12, page 348. The number of additional types of salmonella isolated from humans should read 92, not 82. Thus, the total number of different serotypes isolated is 104, as is correctly stated in the text. Also, the correct total for non-human isolations should be 3078, not 3978.

In addition to the established procedures for reporting morbidity and mortality, the Communicable Disease Center welcomes accounts of interesting outbreaks or cases. Such accounts should be addressed to:
